I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

I also certify that by virtue of an assignment registered under the Patents Act 1977, the application is now proceeding in the name as substituted.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., p.l.c., P.L.C. or PLC.

Registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

Method and Apparatus for Forming a Head on a Beverage

The present invention relates to a method and apparatus for forming a head on a beverage, and in particular on a beverage which contains gas in solution. The gas in solution may be carbon dioxide, nitrogen or any other inert gas suitable for the purpose. The beverage may be alcoholic or non-alcoholic, but the present invention is particularly suited for use with beverages such as beer, lager, ale and stout, where the presence of a head on the beverage when it is presented to the consumer in a drinking vessel is traditional and desirable.

Several different methods of forming a head on a beverage have been proposed, including various means employed when the beverage is dispensed from a keg or similar bulk container into a drinking vessel. Such means, for example, include a device known as a sparkler which disturbs the flow of the liquid such that the gas in the liquid is encouraged to come out of solution. It is not always possible for a bar or similar outlet to store beverages in bulk containers such as kegs, however, primarily due to space and cost constraints. The space needed to store kegs is clearly significant, and the associated dispensing and chilling equipment also involves significant cost for the proprietor. Many establishments therefore concentrate on selling beverages stored in bottles or cans, which are usually kept in display fridges behind the bar. However, this then presents the problem that, when transferring the beverage from a bottle to a glass, conventional methods of head generation employed with keg or barrel delivery systems cannot be employed.

It is known to employ ultrasonic excitation to produce or increase a head on a beverage. The ultrasonic excitation causes cavitation of the liquid which encourages the gas in the liquid to come out of solution. The gas thus forms as tiny bubbles which migrate to the surface of the liquid, forming a head of froth on the surface. The equipment required is relatively straightforward and does not require much space, and therefore is suitable for use in establishments of the type discussed above which stock only bottled or canned beverages and which may have space constraints.

GB-A-1588624 (Arthur Guinness Son & Company) discloses the use of ultrasonic vibration to form a head of froth. The beer is poured manually from a bottle into a glass, the glass is then placed on a platform of an ultrasonic transducer and the ultrasonic vibration is switched on for a time sufficient to produce the desired head.

GB-A-2166715 (Bass plc) also relates to forming a head ultrasonically. In one embodiment, a shallow metal dish with an electromagnetic transducer on its underside is recessed into a bar counter. After a glass of beer has been dispensed, the glass is placed in

the dish and the transducer is operated under the control of a timer to generate the ultrasonic vibrations which form the head.

5 In both the above prior art systems, the use of water to improve the coupling between the ultrasonic platform and the glass is suggested. Even if a glass or drinking vessel is designed to have a flat base, the base will rarely be perfectly planar due to the nature of the material and the way the glass is manufactured. Therefore, if the glass is placed on a dry platform, the vessel will contact the platform only at a few points and an air gap will exist elsewhere between the two. This air gap greatly reduces the efficiency of the transfer of
10 ultrasonic energy to the glass. By providing a water-filled ultrasonic bath, as is suggested in the prior art, water fills the gaps between the glass and platform, and also surrounds at least the lower portion of the glass, thus improving the efficiency of the energy transfer.

15 There are certain disadvantages with the use of an ultrasonic bath according to the prior art for the production of a head on a beverage contained in a glass or other vessel. Primarily, the system requires human intervention to maintain the water level in the bath at the optimum level. The water level will fall in use, as some will inevitably be removed each time a glass is taken out of the bath, and the ultrasonic energy also causes a small amount of water to evaporate each time the transducer is activated. Clearly, it is undesirable to rely
20 on human intervention (especially busy bar staff) to keep the water level topped up.

It is therefore an object of the present invention to provide an improved method and apparatus for forming a head on a beverage that overcomes the aforementioned problem, particularly a simple to use device that does not require the user to perform multiple
25 operations.

According to a first broad aspect of the invention there is provided an apparatus for the formation of a head on a beverage contained in a vessel, including an ultrasonic oscillator for generating an electric signal having an ultrasonic frequency, a transducer connected to
30 the oscillator for converting the electrical signal into a physical ultrasonic excitation, a contact surface coupled to the transducer, onto which the vessel containing the beverage is placed in use, wherein means is provided for maintaining an hydrated layer on the contact surface throughout the period of use.

35 The provision for maintaining a constant, particularly self replenishing, hydrated layer is a new departure in the field of the invention.

The word "coupled" is intended not to exclude there being additional components between the contact surface and the transducer. For example, the contact surface may be mounted or located on a platform or tray which is in turn mounted on the transducer. Thus, the word "coupled" may include arrangements wherein the contact surface is not directly adjacent or part of the transducer. However, it is of course necessary for the ultrasonic excitation to be adequately transmitted to the contact surface in any physical arrangement

In one embodiment the means by which a constant ultrasonic conductive layer is maintained is a hydrophilic material.

The hydrophilic material should have a relatively high water content (preferably 65-70%), and is preferably substantially saturated. In this way, there will be sufficient water between the transducer and vessel that the transfer of ultrasonic energy will be improved compared to a "dry" transfer arrangement. Notably, even in the case where the hydrophilic material is substantially saturated, it is not "wet" in appearance.

Thus, by using a hydrophilic material the present invention provides a system for the transfer of ultrasonic energy to a drinking vessel having the advantages of a "wet" ultrasonic bath as discussed above due to the presence of water between the vessel and the transducer, but without the disadvantages. The hydrophilic material will mould to the bottom of the glass for complete contact and can be wiped clean in the event of any spillages.

A preferred hydrophilic material for use in the present invention is Hydrogel (trade name). This is essentially a plastic material having a relatively high water content (30 - 80%) that has been used to form disposable contact lenses. Materials such as Hydrogel, due to their relatively high water content, behave like water in the way they transmit ultrasonic energy, but do not present the disadvantages associated with water baths as discussed above. Hydrogel is also flexible and resilient when saturated, and therefore is able to readily mould to the contours of the base of a drinking vessel in use, such that the coupling between the transducer and vessel is optimised. The preferred thickness of Hydrogel is 1mm. While this material (and water) is a much more effective conductor than air, ultrasonic energy still decays very swiftly, therefore it is preferable to have as thin a layer as possible. In order to reduce the risk of mould growth etc., the hydrophilic material may contain an anti-bacterial or anti-fungal agent (eg. Microban).

Depending on the type of hydrophilic material and the manner of its use, the material may not require any maintenance to keep it sufficiently hydrated. The material may be such

that evaporation of water from its surface is relatively slow or such that any water loss therefrom is offset by water or other liquid present on the vessel when it is brought into contact with the material, thus automatically maintaining the material in a sufficiently hydrated condition. Water may be present on the base of the glass by virtue of condensation, for example, if the liquid it contains is sufficiently chilled.

Some materials may require periodic rehydration or maintenance to keep them in a hydrated condition. This could be effected manually by the operator, by simply wetting the surface of the material at intervals, e.g. once before use or perhaps when the material is being cleaned, with a spray. The material should preferably remain sufficiently hydrated for the time that the establishment is open. Manual dehydration could be effected by placing the material in a bath of water once the premises are closed, rehydrating the material in preparation for the next session.

Ideally, however, the hydrophilic material is maintained in a sufficiently hydrated condition without reliance on human intervention. Preferably therefore, the apparatus in accordance with the invention further comprises means for maintaining the hydrophilic material or contact surface in a hydrated condition.

In a second embodiment (which may also but not necessarily feature a hydrophilic material on the contact surface) the means by which a constant ultrasonic conductive layer is maintained is by way of a self replenishing hydrating surface.

More preferably, the contact surface comprises a tray having a raised edge, such that a water film or layer is contained on the apparatus and does not drain off.

The maintenance of the hydrophilic material in a hydrated condition and/or the maintenance of a film or layer of water on the contact surface or platform can be performed by similar apparatus, which will be referred to as "hydration means" below.

Suitable hydration means for use in preferred embodiments of the invention may be totally automatic, in that no human operation or intervention is required at any time during normal operation of the device, or it may be semi-automatic in that periodic checking and/or maintenance may be required. It is however preferable that any periodic maintenance intervals are as long as possible. It will be clear to the reader which devices described below belong to which category.

As an example, the hydration means can comprise a refrigeration means. Preferably, means are provided for chilling the hydrophilic material or tray as appropriate to a temperature below that of the ambient environment. In this way, atmospheric moisture will condense on the surface and will thus hydrate it. Preferably, the refrigeration means
5 chills the surface to a temperature below the dew point of the surrounding atmosphere, and more preferably to between about 0°C and about 5°C.

It will be apparent to the skilled person that there are many different ways of chilling the surface of the hydrophilic material or contact surface, all of which would be acceptable. In
10 some establishments, there already exists a supply of refrigerant (such as chilled water or other cooling liquid) and this may be conveniently utilised in the present invention to minimise capital outlay. The refrigerant may simply be piped through the apparatus and returned to the refrigeration unit. Thus, in this embodiment, the refrigeration means preferably comprises a passage through the apparatus through which, in use, a refrigerant
15 may be passed such that the contact surface is sufficiently chilled and atmospheric moisture condenses on the surface thereof. The apparatus may further be provided with inlet and outlet ports in communication with the interior passage, and optionally the passage may be provided with a chamber.

20 Alternatively, it may be necessary to provide the apparatus with its own cooling system, such as a refrigeration unit based on a conventional design or any other e.g. thermo-electric.

In accordance with other embodiments, the hydration means preferably comprises a
25 hydration system in which water is fed to the hydrophilic material or tray. The water may be fed direct from the water supply system of the establishment, or may be supplied from a reservoir which is part of the apparatus. The reservoir may require periodic checking and refilling, or may be provided with automatic refilling means, such as a float-controlled valve or ball valve for example. The reservoir may be provided with level indication
30 means which gives the operator an indication of the water level inside and/or an indication of when the reservoir requires refilling. The water may be fed to the hydrophilic material or surface simply under gravity, by pump or by wicking.

35 However, the preferred embodiment features a contact surface comprised of a platform (note that a recessed tray is not mandatory) onto which a measured quantity of water is pumped from below. Such an arrangement requires the platform to have an aperture (e.g. centrally) in its surface through which a 'shot' of water e.g. 1 or 2 mL is pumped just before the transducer is activated. Such a transducer, coupled below the aperture in the

platform, will be donut shaped so as to have a tube delivering the shot of water passing therethrough. The pump would most appropriately be a peristaltic type pump for this application, but could be any type of pump or valve capable of delivering a preset amount.

5 Preferably successful use of the apparatus occurs in one user operation, i.e. the glass of beverage is placed upon the platform and a switch activates in sequence firstly the pump to deliver a water shot and secondly the ultrasonic transducer to deliver ultrasonic energy to the now water saturated base of the glass.

10 As a further improvement in the field of producing a head of froth on a beverage by means of ultrasonic excitation, the applicant has developed a system which optimises the transfer of ultrasonic energy to the vessel and thus to the beverage. This improved system is capable of application with any of the embodiments and preferred features thereof discussed above.

15 A further problem identified with prior art ultrasonic frothing devices is the apparently inconsistent nature of the device depending on the type of glass used. The basis for using ultrasonic energy as a frothing method lies in the ability to provide a resonant frequency. However, the exact value of the resonant frequency will vary slightly depending on the
20 thickness of the glass base. The prior art did not account for this and therefore some unreliability could arise during use of the device from one glass to another.

Therefore it is a further object of the invention to provide a method for forming a head on a beverage that can effectively form said head over a range of glass thicknesses and types,
25 thereby becoming more reliable.

Therefore, in accordance with a second aspect, the present invention provides a method of forming a head of froth on a beverage contained in a vessel, comprising the steps of:
generating an electrical signal having a variable ultrasonic frequency, converting the
30 electrical signal into a physical ultrasonic excitation, subjecting the vessel containing the beverage to the ultrasonic excitation for a predetermined time, and during the predetermined time, varying the frequency of the electrical signal such that the vessel and beverage are subjected to a predetermined range of ultrasonic frequencies.

35 By use of this method the glass, whatever the base thickness (within limits), is ensured to be subjected to the required resonant frequency for at least a fraction of the application time. It is noteworthy that even this fraction of a time (which may amount to hundredths of a second) is sufficient to cause the required excitation.

In a preferred embodiment electronic circuitry is employed to effect monitoring of the electrical signal to determine the frequency at which maximum resonance of the vessel and beverage is achieved and then maintaining the excitation at this maximum resonant frequency for the remaining time of application of the excitation. Preferably, the ultrasonic frequency is varied at the start of the predetermine application time so the maximum length of time is available at the "optimised" frequency.

The method of the invention thus provides a more efficient transfer of ultrasonic energy for a wide range of vessels and beverages, which might even permit a reduction in the ultrasonic application time in some circumstances.

This aspect also extends to apparatus for carrying out the method defined above. More specifically, in accordance with a third aspect, the present invention provides apparatus for forming a head of froth on a beverage contained in a vessel, comprising:

- an ultrasonic oscillator for generating an electrical signal having a variable ultrasonic frequency;

- a transducer connected to the oscillator for converting the electrical signal into a physical ultrasonic excitation;

- a surface coupled to the transducer, onto which the vessel containing the beverage is placed in use to be subjected to the ultrasonic excitation for a predetermined time;

- and a control means such that, during the predetermined application time, the frequency of the electrical signal is varied such that the vessel and beverage are subjected to a range of ultrasonic frequencies.

In one embodiment the control means is provided to monitor and adjust the frequency to determine a maximum resonance of the vessel and beverage.

It is envisaged that there will be a number of different ways of measuring when the vessel and beverage are in resonance, all of which will be acceptable in the present invention. Preferably, the means for monitoring the electrical signal monitors the current being drawn by the transducer circuit. At resonance, a peak in current will occur, and this peak in current will trigger the maintenance of the applied ultrasonic excitation at the frequency being applied when the drop in current occurs.

The total application time for either the basic or advanced method is preferably between one and two seconds.

The method and apparatus for forming a head on a beverage according to the present invention will now be described in further detail by reference to the accompanying drawings that illustrate preferred embodiments wherein:-

5 Figure 1 is a general overview of one embodiment of the present invention, also showing a standard glass vessel,

Figure 2 is a section view of a further embodiment of the invention,

10 Figure 3a is a section view of a preferred embodiment of the invention utilising a bottom fed platform, while Figure 3b is a general view of a transducer as used in Figure 3a,

Figure 4 is a section view variant of the embodiment from Figure 3, also incorporating an hydrophilic material,

Figures 5a and 5b are section view variants of yet a further embodiment of the present invention,

15 Figure 6 is a further embodiment relying on a wick feed of moisture,

Figure 7 is a further embodiment relying on a pump means, and

Figures 8a and 8b are graphic representations of a method of achieving consistent results from a device for forming a head on a beverage in accordance with the present invention.

20 Referring firstly to Figure 1, a standard glass G (e.g. 1 pint) is illustrated to be placed on apparatus, generally denoted 10, for forming a head on the beverage within glass G. The "flat" beverage (i.e. not fizzy and with a low level of gas out of solution) is preferably filled in the glass up to a level just below the rim, such that the remaining area is to be
25 filled with a head. For the intended purpose of the present invention, the vessel delivering the beer is a bottle which will be a standard volume, hence the pourer will not need to measure out a specified amount to ensure room is left for a head.

30 It will be apparent that the present invention is also useful for forming a head on draught beer straight from a tap, without the need for sparkler type devices as described in the preamble.

35 As visible in Figure 1 the apparatus 10 includes a generally circular tray 11 that includes a shallow recess portion 12. Such a recess 12 may contain a quantity of water or, as illustrated, an hydrophilic material 13. Material 13 may be, by way of example, Hydrogel formed into a thin disc (1mm thick) that is roughly dimensioned the same, or slightly larger, as the diameter of a base B of glass G.

Hydrogel 13 has a water content of, preferably, 65 to 70% to provide a soft contact surface upon which the base B may be placed. The very nature of the Hydrogel 13 means it contacts the substantive surface of base B, with no air gaps as can occur on a "dry" surface.

5 Not shown by Figure 1 is an ultrasonic crystal coupled underneath the contact surface 12 of tray 11. Ultrasonic energy is transferred through the tray (as is known by the prior art) then through the Hydrogel and into the glass of beverage wherein gas in solution is excited to cavitate, rising fine bubbles to the surface that then form a froth ("head").

10 In this basic embodiment the Hydrogel is expected to retain its moisture content for a prolonged period and, in any event, considerably longer than an equivalent 1mm layer of water would last. The Hydrogel covered contact surface 12 is thus relatively self sufficient, at least so far as required for one evening's use. Hydrogel 13 can then be replenished by leaving it to saturate in a small bath of water.

15 Figure 2 illustrates a second embodiment of an apparatus 10 according to the invention. In this example, an ultrasonic transducer (crystal) 14 is visible on the underside of a hollow disc shaped element 15, also featuring a shallow recessed portion 12, much the same as tray 11 of Figure 1. Wires 16 carry alternating current from a control unit, not illustrated, that causes transducer 14 to vibrate.

20 As a means of maintaining a layer of moisture within recess 12, chilled water is passed from an input end 17 toward an output end 18 of hollow disc 15. The chilled water causes a lowered temperature of contact surface 19 and hence condensation to form from the ambient air. The constant layer of water needed for substantive contact with base B can therefore be provided without the need for Hydrogel (but could be used in combination with Hydrogel).

25 It will be noted from Figure 2 that the arrangement of the output end tube 18 is such that chilled water cannot exit from disc 15 until it is at least in contact with the inside of surface 19. It is imperative to maintain the chamber within disc 15 completely full of water, otherwise ultrasonic energy cannot transfer from transducer 14, through the chilled water into surface 19 where it is passed (via condensation) to glass G.

30 Figure 3a illustrates a preferred embodiment of the apparatus 10 according to the present invention wherein a specified amount (e.g. a 1 or 2 mL "shot") of water S is pumped up (or by mains pressure in combination with a valve) through an aperture 20 in the contact surface (platform) 19. The water is supplied immediately prior to activating transducer 14

so that, in practice, only a single operation is required to be performed by the human operator because the steps can be automated in sequence.

5 As illustrated by the sectional view of Figure 3a, and detailed by Figure 3b, transducer 14 is donut shaped in that it has a central hole 14a that surrounds a tube 21 for delivering water through the aperture 20.

10 A variety of electric or mechanical pump means can be used to effect pumping of water into/onto contact surface 19. In one form, the ultrasonic platform may have the get-up of a traditional beer pump/handle for drawing a draught of beer into a glass. Therefore the handle pumping action of the operator may cause a mechanical pump to deliver water to contact surface 19 and then, at the end of the pull, an electric switch will trigger to activate the ultrasonic transducer.

15 Further embodiments may be developed wherein an ultrasonic platform is integrated into a conventional tap configuration, the ultrasonic device being activated after the beer is poured from the tap (all on one platform) to form a head. This alleviates the need for sparkler or other excitation means.

20 Figure 4 illustrates a variation on the central delivery method of Figure 3a by use of a reservoir 22 for maintaining a constant delivery of water. An hydrophilic material 13 as aforementioned is clipped in recess 12 and kept almost indefinitely hydrated by the water from reservoir 22 via tube 21. Reservoir 22 must be periodically refilled.

25 Figures 5a and 5b are a further variation from the reservoir 22 illustrated by Figure 4.

Reservoir 22 side feeds into recess 12 wherein Hydrogel absorbs the moisture for maintaining contact with glass G.

30 Figure 5b shows the reservoir twisted about a tubular coupling 23. It is then unscrewed from a lid 24 and refilled.

The foregoing arrangements are effective but likely to be cumbersome in use.

35 Figure 6 shows an embodiment of the apparatus 10 that could be recessed into a bar top 25 wherein one or more wicks 26 communicate water from a reservoir 27 to the contact surface, in this case Hydrogel 13.

Figure 7 is a variation on the automated pump illustrated by Figure 3a wherein water is delivered from the side and/or above contact surface/Hydrogel 13. The tray 11 further has a drain 28 to remove excess water.

Each of the foregoing embodiments illustrated has the common feature of ensuring that there is substantial conductive contact between the base of the glass and the contact surface being acted on by the ultrasonic transducer for the time required to perform the ultrasonic excitation, whether it be a relatively permanent hydrated layer or "on-demand" as in Figure 3a.

However, little or no excitation may occur if the ultrasonic frequency generated by the transducer is not specific to the requirements of the particular glass. Therefore it is necessary to have a suitable control means to activate transducer 14.

In other ultrasonic applications it is generally desirable to produce apparatus wherein the physical ultrasonic transducer (often a composite of sandwiched materials) is tuned (i.e. machined to a desired thickness) to the generator electronics. However, with the present invention it is more desirable to adjust the generated signal to a frequency that matches resonance of the transducer/tray apparatus 10. This makes manufacture considerably cheaper.

The range of frequencies for current supplied to the transducer will be fixed at manufacture. These will generally be in the order of 20kHz to 80 kHz. But while it is possible to calculate the required frequency for the transducer acting on an "average" glass base, this will rarely be an exact match due to the inherent variations in the glass.

The control means therefore generates a frequency that varies over time around a median which corresponds to the resonant frequency required for an "average" glass. Figure 8a illustrates this deliberate variation in simple graphical form.

The y axis of Figure 8a represents frequency in kilohertz against the x axis for time. The total time that the apparatus is switched on, by way of example, is two seconds in Figures 8a and 8b.

At time 0 the apparatus initially generates an alternating current at 40 kHz (used solely by way of example for the purposes of explanation, this parameter will vary depending on materials used in manufacture etc and can be determined by those skilled in the art). 40kHz

represents the median M frequency required for excitation of an 'average' glass of beer. However the actual frequency required may be above or below this. Dotted line A represents this unknown quantity. Dotted lines R_U and R_L represent the upper and lower ranges of frequency that the device will generate. So long as the unknown frequency A falls within this range R_U and R_L excitation of the beverage is ensured even if for a brief fraction of the overall time. As shown by the graph resonant frequency is reached every time the plotted line crosses the dotted line A.

The ranges R_U and R_L illustrated are 45kHz and 35kHz respectively. This is perhaps exaggerated from practice where the "sweep" of frequencies may be only a few kilohertz.

Figure 8b illustrates a further embodiment wherein the control means 'scans' for the unknown quantity A. Frequency generation begins as in Figure 8a, however, when the control means senses resonance it performs iterative sweeps to 'lock' onto the resonant frequency. As described in the preamble such a sensing means can look for a simple peak in power drawn by the transducer. Over time (a split second) the control means can adjust the frequency to where the power drawn is greatest and hence achieve maximum resonance. The remainder of the excitation time is therefore performed at maximum resonance.

It is further observed that pulsing current to the transducer can increase excitation effectiveness of the apparatus. This can be applied to either of the methods described.

The method and apparatus according to the present invention as hereinbefore described is primarily advantageous because it is simple to use. The apparatus can be manufactured in a number of guises using available materials. Ideally the unit will be compact and fit comfortably into a commercial bar type of environment. It provides not only a practical benefit in that the appearance and taste of the beer is enhanced, but also a uniqueness by virtue of the process that will catch the attention of the consumer. Prior art ultrasonic methods have not been widely adopted because of the problems experienced. The present invention reintroduces the technology in an improved form.

What We Claim is:

1. An apparatus for the formation of a head on a beverage contained in a vessel,
including an ultrasonic oscillator for generating an electric signal having an
ultrasonic frequency, a transducer connected to the oscillator for converting the
electrical signal into a physical ultrasonic excitation, a contact surface coupled to
the transducer, onto which the vessel containing the beverage is placed in use,
wherein means is provided for maintaining an hydrated layer on the contact surface
substantially throughout a period of use.
2. The apparatus of claim 1 wherein means for maintaining the hydrated layer is a
hydrophilic material.
3. The apparatus of claim 2 wherein the hydrophilic material is Hydrogel.
4. The apparatus of claim 3 wherein the Hydrogel is substantially 1 to 2mm thick and
includes a surface area substantially corresponding to a base of the vessel
containing the beverage placed thereon, in use.
5. The apparatus of any one of claims 2 to 4 wherein the hydrophilic material includes
an antifungal or antibacterial agent.
6. The apparatus according to any one of the preceding claims wherein a refrigeration
circuit is arranged to pass by adjacent the contact surface.
7. The apparatus of claim 6 wherein the contact surface has a chamber therebelow
including an input and output end for coupling with the refrigeration circuit to
allow refrigerant to pass therethrough.

8. The apparatus of any one of claims 1 to 5 wherein the contact surface comprises a platform .

5 9. The apparatus of claims 8 wherein the platform includes a recessed portion at least corresponding in area to a base of the vessel intended for use.

10. The apparatus of claim 8 or 9 wherein means is provided to control a supply of water to the recess portion of the platform.

10 11. The apparatus of claim 8, 9 or 10 wherein an aperture is provided in the platform.

12. The apparatus of claim 11 wherein a measured amount of water is supplied to the platform through the aperture.

15 13. The apparatus of claim 12 wherein the measured amount is 1 to 2 millilitres.

14. The apparatus according to any one of claims 8 to 13 wherein a reservoir is provided to supply water to the platform.

20 15. The apparatus according to any one of claims 8 to 13 wherein a mains water supply is coupled to the apparatus for delivery to the platform.

16. The apparatus of claim 14 wherein a wick means is provided between the reservoir and the platform.

25 17. A method of forming a head of froth on a beverage contained in a vessel, comprising the steps of generating an electrical signal having a variable ultrasonic frequency, converting the electrical signal into a physical ultrasonic excitation, subjecting the vessel containing the beverage to the ultrasonic excitation for a

predetermined time and, during the predetermined time, varying the frequency of the electrical signal such that the vessel and beverage are subjected to a predetermined range of ultrasonic frequencies.

5

18. The method according to claim 17 wherein the range is 20 to 80 kHz.

19. The method according to claim 17 or 18 wherein the electrical signal is monitored to identify a peak in power (occurring at resonant frequency) and the frequency is maintained at this identified level for the remainder of the predetermined time.

10

20. Apparatus for forming a head of froth on a beverage contained in a vessel comprising an ultrasonic oscillator for generating an electrical signal having a variable ultrasonic frequency, a transducer connected to the oscillator for converting the electrical signal into a physical ultrasonic excitation, a surface coupled to the transducer, on to which the vessel is placed in use to be subjected to the ultrasonic excitation for a predetermined time, and a control means such that, during the predetermined application time, the frequency of the electrical signal is varied such that the vessel and beverage are subjected to a range of ultrasonic frequencies.

15

20

21. The apparatus of claim 20 wherein the control means further monitors for maximum resonance of the beverage and vessel by measuring the power being drawn by the transducer.

25

22. The apparatus of claim 21 wherein the control means substantially maintains the maximum resonant frequency for the remainder of the application time.

23. The apparatus of any one of claims 20 to 22 wherein the control means pulses the electrical signal for a plurality of predetermined times.

24. The apparatus of claim 20 where the predetermined time is up to 2 seconds.

ABSTRACT

METHOD AND APPARATUS FOR FORMING A HEAD ON A BEVERAGE

5 A method and apparatus of forming a head on a beverage using ultrasonic energy, the apparatus (10) including an hydrating means (13) such that a layer of water is provided to keep a platform (19), which is in turn coupled to an ultrasonic transducer (14), maintained in conductive contact with the base (B) of a glass (G) of beverage. The water layer improves the transfer of ultrasonic energy to the beverage in the glass. Preferably the
10 method and apparatus also features a control means to provide a range of ultrasonic frequencies to the ultrasonic transducer to take into account variations in glass base thickness that otherwise makes energy transfer inconsistent.
